**Abstract**

**Background**

Hydatidosis is a chronic cyst forming helminthic disease of human, domestic and wild animals. The immune responses play a pivotal role in limiting cystic larval development.

**Objective**

To investigate the immunopathological effects of *Fasciola hepatica* antigens (FHAgs) and hydatid cyst fluid antigens (HCFAs) on the immune response against hydatidosis in mice.

**Methods**

One hundred mice were divided into 5 groups; the 1\(^{st}\) three were immunized subcutaneously with 0.2 ml of HCFAs, FHAgs and mixed antigen (MAg = HCFAs+FHAgs), respectively. The last two regarded as control groups. On day 27 post immunization, the skin test was done for the 1\(^{st}\) four groups. On day 30, half the animals of each group were scarified to perform E-rosette test, agar gel diffusion (AGD), and ELISA test. The rest of the mice with the 5\(^{th}\) group were challenged with 2000 viable protoscolex / mouse. After 3 months, they were scarified for gross and histopathological examination.

**Results**

The immunized group with MAg was hypersensitive prior to challenge the skin test, while E-rosette test indicated the highest ratio of active lymphocytes before and after challenge in comparison with other groups. The AGD test showed severe reaction between the sera of mice immunized with MAg against the FHAgs against HCFAs and between sera of immunized group with FHAgs against HCFAs and vice versa. The highest level of antibodies was recorded in the immunized group with MAg. Histopathological examination for the internal organs of immunized groups revealed granulomatous lesions, reduction in the number of cysts with lymphocytic hyperplasia and presence of degenerative protoscolices. Control infected group revealed growth of cysts in the internal organs, with degenerative and necrotic lesions.

**Conclusion**

The 3 types of Ags stimulate humoral and cellular immunity was proved by immune-histopathological investigations. The MAg was highly immunogenic in comparison with each Ag alone. This antigenic activity may be due to the presence of synergistic interactions and cross-reactivity between the 2 parasites and this can be used as protective value against hydatidosis in the intermediate hosts.

**Keywords**

Parasitic infections, immunological cross reaction, isolation parasitic antigens, *Fasciola hepatica* antigens, Hydatid fluid antigens.

---

**List of abbreviation:** CE = cystic echinococcosis, AE = alveolar echinococcosis, Ags = antigens, Ab = antibodies, HC = hydatid cyst, PSC = protoscolices, HCFAg = HC fluid antigen, FHAgs = *Fasciola hepatica* antigen MAg = mixed antigen, PBS = phosphate buffered saline, SFHFAg = soluble filtrated hydatid fluid antigens, SFHAgs = sonicated *Fasciola hepatica* antigens, SSFHAgs = soluble sonicated *Fasciola hepatica* antigens, NO = nitric oxide.

**Introduction**

Echinococcosis is a zoonotic parasitic disease caused by the adult or larval stages of the cestodes belong to the genus *Echinococcus* (family Taeniidae). Larval infection (hydatid disease, hydatidosis) is a chronic cyst forming helminthic disease of human beings as well as domestic and wild animals \(^1\). The important medical and public species are *Echinococcus granulosus*, and *Echinococcus multilocularis*, which cause cystic echinococcosis (CE) and alveolar echinococcosis (AE), both are serious diseases \(^2\). The AE
especially with poor prognosis if careful clinical management is not conducted (2,3).

The immune responses play a pivotal role in limiting cystic larval development. Lightowlers et al (4) reported that the vaccine conferred a high degree of protection against challenge with different geographical isolates of Echinococcus granulosus (E. granulosus). Then results indicate that vaccine could have wide applicability as a new tool for use in hydatid disease control campaigns (5).

In another experiment, Hashemi and Razmi (6) reported that the antigens (Ags) of whole body of E. granulosus, might be a good candidate for immunization and diagnosis of hydatid cyst (HC) in an intermeditated host. Fasciola hepatica (F. hepatica) has a wide distribution especially in Iraq, and sometimes there is mixed infection of hydatidosis and fascioliasis; and in an attempt to suggest a defined vaccine against HCs and F. hepatica infection, this study were designed (7).

The aims of current study are to evaluate the role of F. hepatica Ags and hydatid fluid Ags against HC infection in mice by performing immuno-pathological studies plus the correlation and assessment of the immunological and the pathological changes with the 3 types of Ags that used for immunization to get a good candidate for immunization and diagnosis of HC in the intermediate hosts.

**Methods**

**Laboratory animals**

Total number of (100) mice (BALB/C) of both genders ranged 4-6 weeks old, and weighted between 19-24 g. They were divided into five groups; each group had 20 mice, 1st, 2nd and 3rd groups were immunized with HC fluid Ag (HCFAg), Fasciola hepatica Ag (FHAg) and mixed Ag (MAg) respectively, 4th and 5th groups were considered as control groups, both treated with phosphate buffered saline (PBS), then the fifth infected with HC and was left for 3 months.

**Preparation of Ags**

Hydatid cyst fluid antigens

According to Moosa and Abdel-Hafez (8), four hundred ml of hydatid fluid was aseptically aspirated from 35 fertile HCs lodged in sheep livers. The fluid containing protoscolices (PSC) and membrane fragments was pooled and centrifuged at 5000 g for 30 minutes at 4 °C to precipitate PSCs. The supernatant was dialyzed and processed according to McVie et al (9) to get HCFAg. The protein concentration was measured using UV-visible spectrophotometer at wave lengths 280 and 260 nm, respectively, it was 3.3 mg/ml. HCFAg antigens was stored at -20 °C till use (immunization), and 20 ml of antigens was centrifuged with ultra cold centrifuge (13000 rpm for 30 minute), supernatant was called soluble filtrated FHAg (SFHFAg) was stored at -20°C till use for skin test.

**Fasciola hepatica Antigens**

Thirty-five adult flukes were collected from livers samples of sheep infected with fascioliasis. The worms were identified morphologically according to Threadgold (10). They were washed and homogenized in PBS pH 7.4 using an electrical homogenizer (ultra-turrax) and processed according to Abdel-Rahman et al (11) to get sonicated Fasciola hepatica antigens (SFHAg). Protein concentration was 4.1mg/ml using UV-visible spectrophotometer at wave length 280 nm, 260 nm respectively, then it was diluted with distal water in order to make its concentration 3.3 mg/ml. SFH Ags was stored in a deep freezer until use. Fifteen ml of the supernatant was centrifuged with ultra cold centrifuge at 13000rpm for 30 min, to get soluble sonicated FHAg (SSFH Ags) then was stored at -20°C till use.

**Preparation of protoscolices and estimating the challenge dose**

PSCs were collected aseptically from 10 fertile E. granulosus cysts, size (4-6 cm) from the liver of infected sheep. The collected PSCs were washed in PBS (PH7.4) containing 100 µg/ml of gentamycin, then the viability and the quantity of PSCs was determined according to Morel (12).

**Experimental design**

One hundred mice divided into five groups as shown in the box below:
Delayed type hypersensitivity test
Delayed type hypersensitivity test was done according to Ohta et al.\(^{[13]}\) for the all animals at 27th day post immunization as shown in fig.1.

Erythrocytes-Rosette test
This test was performed according to Braganza et al.\(^{[14]}\) to evaluate the viability and the activity of isolated T-lymphocytes from blood of immunized and control groups.

Agar gel diffusion test
This test was done according to Bombardier and Ggiordano\(^{[15]}\). 50 µl of pooled sera from each group of mice were isolated from their blood samples, they were diluted serially (1:50, 1:100, 1:200) in carbonate-bicarbonate buffer. Also 10 µl from each antigen was diluted serially (1:2, 1:4, 1:8). Best dilutions for the sera and antigens that gave visible precipitate line in the agar gel diffusion test were used in enzyme linked immunosorbent assay (ELISA)\(^{[16]}\).

Enzyme Linked Immunosorbenent Assay
Determination of specific antibodies was carried out as described by Ferragut and Nieto\(^{[17]}\), with simple modifications briefly, 96-well microtitration plate was coated with 200 µl/well of antigens (HCF, FH or Mix) diluted 1:8 in carbonate-bicarbonate buffer pH 9.6 and incubated over night at 4 °C in a humid chamber. Excess antigen was removed and washing the wells four times with PBS – Tween 20 pH 7.4, and blotting by using a filter paper, then blocking was done with 200 µl of 1% Bovine serum albumin in PBS at 37 °C for 1hr. Wells were dried, and added 200 µl/well diluted sera at a 1:200 dilution in PBS –T20 and incubated 2 hr at room temperature, the plate was washed with PBS – T20 as described above, 200 µl of freshly diluted conjugate (HRP-Goat anti mouse IgG) 1:10000 in diluent reagent 1% BSA-PBS was added in each well and incubated for 3hr at 37 oC in humid chamber. The plate was washed as
described above to remove excess conjugate; 200µl of substrate solution (OPD and H$_2$O$_2$) was added to all well and left for 30 min in a dark place. The reaction was terminated by adding 50µl H$_2$SO$_4$ 2.5 M, the optical density was read on (630) nm with a by bio-tek micro plate reader (model 450).

Preparations of tissue sections
For histopathological study tissue samples were taken from internal organs of immunized and control groups. They were fixed in 10% formalin and processed routinely according to Bancroft and Steven [18].

Statistical analysis
Data were analyzed statistically using the Microsoft Program (SPSS). Statistical analysis of data was performed on the basis of Two-Way Analysis of Variance (ANOVA) using a significant level of ($P$ < 0.05). Specific group differences were determined using least significant differences (LSD) as described by Snedecor and Cochran [19].

Results
The results of delayed type hypersensitivity showed a higher significant ($P$ < 0.05) increase in the means of foot pad thickness of immunized groups as compared with the control. A higher increase of thickness detected in the mice treated with mixed antigen (HCFAg + FHAg) in comparison with immunized and control group as shown in table 1.

Table 1. Foot pad thickness of immunized and control groups at 27th day post immunization.

In the technique of agar gel diffusion test, diffusion of the antigen and anti-sera took place through the agar. Visible precipitin lines are formed in the gel at the point of equivalence. The results showed precipitin bands between sera of immunized mice with M Ag and the HCF Ags and FH Ags. Also precipitin bands observed between sera of infected mice with PSCs and HCF Ags and FH Ags (Fig. 1).

Fig. 1. Agar gel diffusion

ELISA of all immunized mice showed a strong response to the three antigens. The results reveal a significant difference ($P$ < 0.05) between immunized and control groups. A higher level of
Abs (0.462±0.009) is found in sera of mice immunized with M Ag (Table 3).

### Gross pathological changes

A number of secondary HCs were observed in mice 3 months post infection, unilocular white fluid filled cysts, measuring from 1-2mm mainly in liver and abdominal cavity (Fig. 2). No gross lesions were seen in the examined organs of immunized animals that were scarified after challenge except the presence of variable degrees of splenomegally and hepatomegally with congestion of some organs mainly in the immunized mice with MAg.

### Histopathological changes

In non-immunized infected animals (positive-control group) (Fig. 3) and immunized infected animals were found in different internal organs as shown in fig. 2 through 10 which revealed appearance of HCs in the liver and other internal organs of control infected group, with focal and diffuse amyloid deposition in the spleen. The immunized groups revealed absence of cysts in the liver, presence of granulomatous lesions, appearance of degenerated PSCs, appearance of lymphoid proliferation in spleen and lung (BALT), suppurative pneumonia, and presence of extensive fibrous capsule in the spleen and kidney of mice immunized with M Ag.

![Fig. 2. Macroscopical examination of control group showed multiple unilocular, small secondary hydatid cysts on liver surface (A) and other internal organ (B) three months post challenge](image)

![Fig. 3. Microscopical section in the hydatid cyst of control infected animal three months post challenge showed hydatid cyst with all three layers (germinative, laminated and adventitia (H&E X10)](image)

![Fig. 4. Microscopical section in the spleen of control infected animals three months post challenge showed positive Congo red result (pale pink to red color) with focal and diffuse amyloid deposition (Congored X40).](image)
Microscopical section in the lung of immunized mice with HCF Ags showed hyperplasia peribronchiolar associated lymphoid tissue three months post-challenge (H&E X20).

Microscopical section in the liver of immunized animal with HCF Ags three months post challenge showed moderate MNCs aggregation in liver parenchyma mainly around dilated bile duct with appearance of degenerated protoscolex (H&E X40).

**Fig. 6.** Microscopical section in the liver of immunized animal with HCF Ags three months post challenge showed moderate MNCs aggregation in liver parenchyma mainly around dilated bile duct with appearance of degenerated protoscolex (H&E X40).

**Fig. 7.** Microscopic section in the lung of immunized animal with FH Ags showed suppurative pneumonia three months post challenge (H&E X40).

**Fig. 8.** Microscopical section in the spleen of immunized animal with M Ag, three months post challenge showed increase thickening of capsule with fibrosis together with congestion of red pulp (H&E X40).

**Discussion**

Skin test (delayed type hypersensitivity-DTH)

We suggest that the parasitic Ags (immunization or mixed infection) synergistically interact with each other and probably an important influence on the immune system. Also this could be due to presence of similar epitops in both parasitic Ags that is responsible for the cross-reactive effect against hydatidosis in sheep. The formation of rosettes is a specific test for cells of T lineage. The results can be due to that these antigens stimulate cellular immune response through activation of T-lymphocytes.

The results of agar gel diffusion test may be due to the presence of common Ags in different parasites react against same antisera. The results of ELISA were in agreement with Babba et al., Poretti et al., Lin et al., and Gaudier et al.
The results of this study proved a synergism and across reaction between two economically important zoonotic helminthes belong to different classes. This cross reaction was observed by ELISA in which Abs raised against one Ag cross reacted with the other antigens (11,20,21,22).

The appearance of HCs in the liver of control infected group associated with vacuolar and necrotic changes as well as atrophy of splenic white pulp indicate that PSC reached the liver through the peritoneum where the parasite developed and overcome the host defense with its secretion of immune complexes that inhibit immune mechanism of infected host (29). The absence of cystin the liver of immunized groups with HCF Ags and M Ag indicate that the immune response prevent the PSC to develop in the host (7). Vuitton (30) suggested that parasite may avoid the host immune system because of low immunogenicity by masking surface Ags as well as interfering with Ag-presenting mechanism.

As well as granulomatous lesion (Fig. 10) may also be seen in the examined organs at three months post challenge in the immunized groups due to the host defense mechanism which attempts to localize and destroy the PSC through inducing proliferation and aggregation of phagocytic cells mainly alternative activated macrophage which produce cytokines IL-8 and IL-12. Also the present results reveal the appearance of degenerated PSCs in the liver of immunized group with HCF Ags (Fig. 6) this may be due to the crucial and important role of IL-12 in the inhibition of larval growth, and was originally termed natural killer cell (31). The appearance of lymphoid proliferation in spleen and lung (BALT) (Fig. 5) showed hyperplastic changes as a result to its persistent stimulation by HCF Ags especially 3 months P.I that revealed a good immune response following PSC infection which act as a mitogen stimulate lymphoid cells. Suppurative Pneumonia which was noticed in the present study (Fig. 7) may be due to the deposition of immune complexes as a result of pulmonary tissue injury (7,32).

The spleen revealed lymphoid depletion in the immunized group with Fasciola hepatica Ags, this may be due to the role of nitric oxide (NO), the FH excretory/secretory antigens decrease nitrate production by host peritoneal cells, a mechanism to avoid an immune response during the first stage of liver penetration. This could explain the transient suppression observed in spleen mononuclear cell proliferation response; on the other hand NO production could also be
one of the strategies of parasite to avoid potential killing effect of NO during peritoneal migration.\(^{33}\) The presence of extensive fibrous capsule in the spleen (Fig. 8) and kidney of mice immunized with M antigen (Fig. 9) refers to the potential role of M antigen in activating and stimulating the host immune response and this capsule protects the host against PSCs effect that killed them before development so the results of kidney and spleen fibrosis would tend to cast doubt on the idea that the resistance developed against a challenge of PSC was due to physical barrier presented by extensive capsular fibrosis in kidney and spleen. In conclusion, this study showed that the three antigens (FHAg, HCFAg, and M Ag) stimulate both cellular and humoral immune response, and this is clear in the histopathological observations by preventing the development of HCs in the immunized group with 3 types of Ags. The mixed Ag gave high response for both humoral and cellular immunity. Using mixed Ag gave higher response or reactivity in skin test, E-rosette, ELISA and in agar gel diffusion, while other groups showed less response than the M Ag in comparison to control group due to the synergism and cross-reactivity between the two parasites.
